

Okay,\n\nThe following bullet points summarize the critical components and flows governing the AI development workflow:

* **Development Workflow:** The process leverages three primary tools:

1. **IDE (Integrated Development Environment)**-A comprehensive environment assisting with code writing, including debugging capabilities and project management.\n2. **CLI (Command Line Interface)** - A text-based interface used to execute commands from a terminal/shell, allowing for automated tasks through scripting.\n3. **API (Application Programming Interface)** - Acts as an intermediary for communication between applications and systems, enabling seamless sharing of services across different programs.\n

* **Workflow Stages:**

1. **Prompt Input:** The user initiates work through input of a textual prompt.
2. **API Request:** An Application uses the API to receive the Prompt (text input).
3. **Prompt Forwarding:** API relays this text request from the application to the language model server (cloud backend) via an internet connection.\n
4. **Response Generation & Return:** The LLM server executes and generates a response based on the prompt,\nsent back through the API to the Application, after which its Data is delivered back to the User for display on their screen.
5. **Output Delivery:** Finally, the application showcases the rendered data generated by this system.
